

ABSTRACT OF THE DISCLOSURE

[00029] An under booth paint collection apparatus is positioned beneath a paint application booth that includes an air circulation system for painting a product with particulate paint. A plurality of discrete powder reclamation collectors are arranged in aligned rows beneath the booth. Continuously aligned air chambers are each positioned above one of the opposing rows of reclamation collectors. Each air chamber is defined by having opposed continuous side walls interconnecting said reclamation collectors. Each air chamber provides a continuous air plenum directing air and particulate paint not adhered to the product being painted from the application booth to the plurality of discrete reclamation chambers.
